Unit 4: Regression and Prediction

3. Inference for Linear Regression (Chapter 5.4)

2/24/2020

Quiz 8 - linear regression

Recap from last time

- 1. We can use the slope and intercept of a regression line to make predictions
- 2. We can also sometimes extrapolate, but this can be fraught
- 3. Like other statistics we've explored so far, linear regression models are appropriate only when some conditions are met

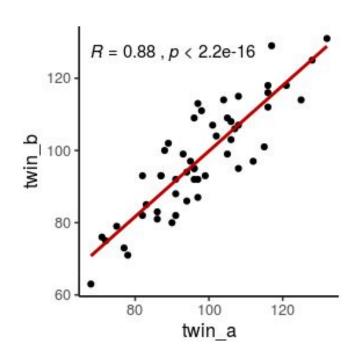

Key ideas

- A regression model's slope codes the relationship between the two measures
- 2. Correlation is equivalent to the slope of a regression for standardized values
- 3. Inference for regression parameters uses t-tests

Nature or nurture?

In 1966 Cyril Burt published a paper called "The genetic determination of differences in intelligence: A study of monozygotic twins reared apart"

The data consist of IQ scores for [an assumed random sample of] 53 identical twins, separated within 6-months of birth and raised apart

Practice Question 1: Interpreting regression output

```
Estimate Std. Error t value Pr(>|t|)
(Intercept) 9.08670 6.92036 1.313 0.195
twin_a 0.90741 0.07004 12.957 <2e-16 ***
```

Residual standard error: 7.417 on 51 degrees of freedom Multiple R-squared: 0.767, Adjusted R-squared: 0.7624 F-statistic: 167.9 on 1 and 51 DF, p-value: < 2.2e-16

Which of the following is <u>false</u>?

- (a) An additional 10 points in one twin's IQ is associated with additional 9 points in the the other twin's IQ, on average.
- (b) Roughly 91% of the variance in twins' IQs can be predicted by the model.
- (c) The linear model is twin_b = $9.08 + 0.91 \times twin_a$.
- (d) Twins in group b with IQs higher than average IQs tend to have biological twins in group a with higher than average IQs as well.

Practice Question 1: Interpreting regression output

```
Estimate Std. Error t value Pr(>|t|)
(Intercept) 9.08670 6.92036 1.313 0.195
twin_a 0.90741 0.07004 12.957 <2e-16 ***
```

Residual standard error: 7.417 on 51 degrees of freedom Multiple R-squared: 0.767, Adjusted R-squared: 0.7624 F-statistic: 167.9 on 1 and 51 DF, p-value: < 2.2e-16

Which of the following is <u>false</u>?

- (a) An additional 10 points in one twin's IQ is associated with additional 9 points in the the other twin's IQ, on average.
- (b) Roughly 91% of the variance in twins' IQs can be predicted by the model.
- (c) The linear model is twin_b = $9.08 + 0.91 \times twin_a$.
- (d) Twins in group b with IQs higher than average IQs tend to have biological twins in group a with higher than average IQs as well.

Practice Question 2: Testing the relationship

Assuming that these 53 pairs of twins are a representative sample of all twins separated at birth, we would like to test if these data provide convincing evidence that the IQ of a biological twin is a significant predictor of IQ of the other twin.

What are the appropriate hypotheses?

$$\hat{y} = \beta_0 + \beta_1 x$$

(a)
$$H_0$$
: $b_0 = 0$; H_A : $b_0 \ne 0$

(b)
$$H_0$$
: $\beta_0 = 0$; H_A : $\beta_0 \neq 0$

(c)
$$H_0$$
: $b_1 = 0$; H_A : $b_1 \ne 0$

(d)
$$H_0: \beta_1 = 0; H_A: \beta_1 \neq 0$$

Practice Question 2: Testing the relationship

Assuming that these 53 pairs of twins are a representative sample of all twins separated at birth, we would like to test if these data provide convincing evidence that the IQ of a biological twin is a significant predictor of IQ of the other twin.

What are the appropriate hypotheses?

$$\hat{y} = \beta_0 + \beta_1 x$$

(a)
$$H_0$$
: $b_0 = 0$; H_A : $b_0 \ne 0$

(b)
$$H_0$$
: $\beta_0 = 0$; H_A : $\beta_0 \neq 0$

(c)
$$H_0$$
: $b_1 = 0$; H_A : $b_1 \ne 0$

(d)
$$H_0: \beta_1 = 0; H_A: \beta_1 \neq 0$$

Analyzing the slope of the regression line

| | estimate | std.error | t-value | p-value |
|-------------|----------|-----------|---------|---------|
| (Intercept) | 9.0867 | 6.9203 | 1.3130 | 0.1950 |
| twin_a | 0.9074 | 0.0700 | 12.956 | 0.0000 |

We always use a **t-test** in inference for regression.

Remember: test statistic $T = (point\ estimate\ -\ null\ value)\ /\ SE$

Point estimate: b_1 is the observed slope. SE_{b1} is the standard error of the slope.

Degrees of freedom of the slope is df = n - 2, where n is the sample size.

Remember: we lose 1 degree of freedom for each parameter we estimate, and in simple linear regression we estimate 2 parameters, β_0 and β_1 .

Analyzing the slope of the regression line

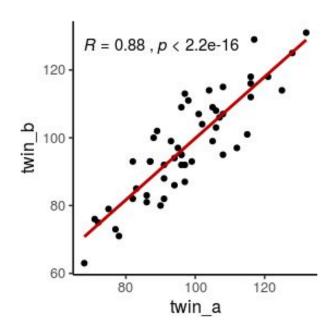

| | estimate | std.error | t-value | p-value |
|-------------|----------|-----------|---------|---------|
| (Intercept) | 9.0867 | 6.9203 | 1.3130 | 0.1950 |
| twin_a | 0.9074 | 0.0700 | 12.956 | 0.0000 |

$$T = \frac{.9074 - 0}{.0700} = 12.956$$
$$df = 53 - 2 = 51$$

$$p - value = P(|T| > 12.956) < .001$$

What is the relationship between slope and correlation?

| | estimate | std.error | t-value | p-value |
|-------------|----------|-----------|---------|---------|
| (Intercept) | 9.0867 | 6.9203 | 1.3130 | 0.1950 |
| twin_a | 0.9074 | 0.0700 | 12.956 | 0.0000 |

Practice Question 3: Confidence intervals for regression estimates

Remember that a confidence interval is calculated as point estimate ± ME and the degrees of freedom associated with the slope in a simple linear regression is n - 2. Which of the below is the correct 95% confidence interval for the slope parameter? (Note that the model is based on observations from 53 twins).

| | estimate | std.error | t-value | p-value |
|-------------|----------|-----------|---------|---------|
| (Intercept) | 9.0867 | 6.9203 | 1.3130 | 0.1950 |
| twin_a | 0.9074 | 0.0700 | 12.956 | 0.0000 |

- (a) 9.0867 ± 1.65 x 6.9203
- (b) $.9074 \pm 2.01 \times .0700$
- (c) $.9074 \pm 1.96 \times .0700$
- (d) $9.0867 \pm 1.96 \times .0700$

Practice Question 4: Confidence intervals for regression estimates

Remember that a confidence interval is calculated as point estimate ± ME and the degrees of freedom associated with the slope in a simple linear regression is n - 2. Which of the below is the correct 95% confidence interval for the slope parameter? (Note that the model is based on observations from 53 twins).

| | estimate | std.error | t-value | p-value |
|-------------|----------|-----------|---------|---------|
| (Intercept) | 9.0867 | 6.9203 | 1.3130 | 0.1950 |
| twin_a | 0.9074 | 0.0700 | 12.956 | 0.0000 |

(a)
$$9.0867 \pm 1.65 \times 6.9203$$

$$n = 53$$
 $df = 53 - 2 = 51$

(b)
$$.9074 \pm 2.01 \times .0700$$

95%:
$$t_{51}$$
* = 2.01

(c)
$$.9074 \pm 1.96 \times .0700$$

$$0.9074 \pm 2.01 \times 0.0700$$

(d)
$$9.0867 \pm 1.96 \times .0700$$

Inference for linear regression

Inference for the slope for a single-predictor linear regression model:

Hypothesis test:
$$T = \frac{b_1 - null\ value}{SE_h}$$
 $df = n - 2$

Confidence interval: $b_1 \pm t_{df=n-2}^{\star} SE_{b_1}$

The null value is often 0 since we are usually checking for **any** relationship between the explanatory and the response variable.

The regression output gives b_1 , SE_{b1} , and **two-tailed** p-value for the t-test for the slope where the null value is 0.

We rarely do inference on the intercept, so we'll focusing on the slope.

Key ideas

- A regression model's slope codes the relationship between the two measures
- 2. Correlation is equivalent to the slope of a regression for standardized values
- 3. Inference for regression parameters uses t-tests
